Abstract: Standard Gini covariance and Gini correlation play important roles in measuring the dependence between random variables with heavy tailed distributions. However, the asymmetry of Gini covariance and correlation brings a substantial difficulty in interpretation. In this paper, we propose a symmetric Gini-type covariance and a symmetric Gini correlation (ρg) based on the joint rank function. The proposed correlation ρg is more robust than the Pearson correlation but less robust than the Kendall’s τ correlation. We establish the relationship between ρg and the linear correlation ρ for a class of random vectors in the family of elliptical distributions, which allows us to estimate ρ based on estimation of ρg. The asymptotic normality of the resulting estimators of ρ are studied through two approaches: one based on influence function and the other based on U-statistics and the delta method. We compare asymptotic efficiencies the symmetric Gini, regular Gini, Pearson and Kendall’s τ linear correlation estimators under various distributions. In addition to reasonably balancing between robustness and efficiency, the proposed measure ρg shows superior finite sample performance, which makes it attractive in applications. Résumé: Insérer votre résumé ici. We will supply a French abstract for those authors who can’t prepare it themselves. La revue canadienne de statistique xx: 1–19; 2016 © 2016 Société statistique du Canada

1. INTRODUCTION

Let X and Y be two non-degenerate random variables with marginal distribution functions F and G, respectively, and a joint distribution function H. To describe the correlation between X and Y, the Pearson correlation (denoted as ρp) is probably the most frequently used measure. This measure is based on the covariance between two variables, which is optimal for describing the linear association between bivariate normal variables. However, the Pearson correlation performs poorly for variables with heavily-tailed or asymmetric distributions, and may be seriously impacted even by a single outlier (e.g., Shevlyakov and Smirnov, 2011). Under the assumption that F and G are continuous, the Spearman correlation, a robust alternative, is a multiple (twelve) of the covariance between the cumulative functions (or ranks) of two variables; the Gini correlation is based on the covariance between one variable and the cumulative distribution of the other (Blitz and Brittain, 1964). Two Gini correlations can be defined as

\[ \gamma(X, Y) := \frac{\text{cov}(X, G(Y))}{\text{cov}(X, F(X))} \quad \text{and} \quad \gamma(Y, X) := \frac{\text{cov}(Y, F(X))}{\text{cov}(Y, G(Y))} \]

to reflect different roles of X and Y. The representation of Gini correlation \( \gamma(X, Y) \) indicates that it has mixed properties of those of the Pearson and Spearman correlations. It is similar to Pearson in X (the variable taken in its variate values) and similar to Spearman in Y (the

© 2016 Statistical Society of Canada / Société statistique du Canada
variable taken in its ranks). Hence Gini correlations complement the Pearson and Spearman correlations (Schechtman and Yitzhaki, 1987; 1999; 2003). Two Gini correlations are equal if \( X \) and \( Y \) are exchangeable up to a linear transformation. However, Gini covariances are not symmetric in \( X \) and \( Y \) in general. On one hand, this asymmetrical nature is useful and can be used for testing bivariate exchangeability (Schechtman, Yitzhaki and Artsev, 2007). On the other hand, such asymmetry violates the axioms of correlation measurement (Mari and Kotz, 2001). Although some authors (e.g., Xu et al., 2010) dealt with asymmetry by a simple average \( \frac{\gamma(X, Y) + \gamma(Y, X)}{2} \), it is difficult to interpret this measure, especially when \( \gamma(X, Y) \) and \( \gamma(Y, X) \) have different signs.

The asymmetry of \( \gamma(X, Y) \) and \( \gamma(Y, X) \) stems from the usage of marginal rank function \( F(x) \) or \( G(y) \). A remedy is to utilize a joint rank function. To do so, let us look at a representation of the Gini mean difference (GMD) under continuity assumption:

\[
\Delta(F) = 4\text{cov}(X, F(X)) = 2\text{cov}(X, 2F(X) - 1) \quad \text{(Stuart, 1954; Lerman and Yitzhaki, 1984)}.
\]

The second equality rewrites GMD as twice of the covariance of \( X \) and the centered rank function \( r(X) := 2F(X) - 1 \). If \( F \) is continuous, \( E r(X) = 0 \). Hence

\[
\Delta(F) = 2\text{cov}(X, r(X)) = 2E(X r(X)). \tag{1}
\]

The rank function \( r(X) \) provides a center-orientated ordering with respect to the distribution \( F \). Such a rank concept is of vital importance for high dimensions where the natural linear ordering on the real line no longer exists. A generalization of the centered rank in high dimension is called the spatial rank. Based on this joint rank function, we are able to propose a symmetric Gini covariance (denoted as \( \text{cov}_g \)) and a corresponding symmetric correlation (denoted as \( \rho_g \)). That is, \( \text{cov}_g(X, Y) = \text{cov}_g(Y, X) \) and \( \rho_g(X, Y) = \rho_g(Y, X) \).

We study properties of the proposed Gini correlation \( \rho_g \). In terms of the influence function, \( \rho_g \) is more robust than the Pearson correlation \( \rho_p \). However, \( \rho_g \) is not as robust as the Spearman correlation and Kendall’s \( \tau \) correlation. Kendall’s \( \tau \) is another commonly used nonparametric measure of association. The Kendall correlation measure is more robust and more efficient than the Spearman correlation (Croux and Dehon, 2010). For this reason in this paper we do not consider Spearman correlation for comparison.

As Kendall’s \( \tau \) has a relationship with the linear correlation \( \rho \) under elliptical distributions (Kendall and Gibbons, 1990; Lindskog, Mcneil and Schmock, 2003), we also set up a function between \( \rho_g \) and \( \rho \) under elliptical distributions. This provides us an alternative method to estimate \( \rho \) based on estimation of \( \rho_g \). The asymptotic normality of the estimator based on the symmetric Gini correlation is established. Its asymptotic efficiency and finite sample performance are compared with those of Pearson, Kendall’s \( \tau \) and the regular Gini correlation coefficients under various elliptical distributions.

As any quantity based on spatial ranks, \( \rho_g \) is only invariant under translation and homogeneous change. In order to gain the invariance property under heterogeneous changes, we provide an affine invariant version.

The paper is organized as follows. In Section 2 we introduce a symmetric Gini covariance and the corresponding correlation. Section 3 presents the influence function. Section 4 gives an estimator of the symmetric Gini correlation and establishes its asymptotic properties. In Section 5 we present the affine invariant version of the symmetric Gini correlation and explore finite sample efficiency of the corresponding estimator. We present a real data application of the proposed correlation in Section 6. Section 7 concludes the paper with a brief summary. All proofs are relegated to the Appendix.
2. SYMMETRIC GINI COVARIANCE AND CORRELATION

The main focus of this section is to present the proposed symmetric Gini covariance and correlation, and to study the corresponding properties.

2.1. Spatial rank

Given a random vector $Z$ in $\mathbb{R}^d$ with distribution $H$, the spatial rank of $z$ with respect to the distribution $H$ is defined as

$$r(z, H) := \mathbb{E}s(z - Z) = \mathbb{E}\frac{z - Z}{||z - Z||},$$

where $s(\cdot)$ is the spatial sign function defined as $s(z) = z/||z||$ with $s(0) = 0$. The solution of $r(z, H) = 0$ is called the spatial median of $H$, which minimizes $\mathbb{E}_H||z - Z||$. Obviously, $\mathbb{E}r(Z, H) = 0$ if $H$ is continuous. For a more comprehensive account of the spatial rank, see Oja (2010).

In particular, for $d = 2$ with $Z = (X, Y)^T$, the bivariate spatial rank function of $z = (x, y)^T$ is

$$r(z, H) = \mathbb{E}\frac{(x - X, y - Y)^T}{||z - Z||} := (R_1(z), R_2(z))^T,$$

where $R_1(z) = \mathbb{E}(x - X)/||z - Z||$ and $R_2(z) = \mathbb{E}(y - Y)/||z - Z||$ are two components of the joint rank function $r(z, H)$.

2.2. Symmetric Gini covariance

Our new symmetric covariance and correlation are defined based on the bivariate spatial rank function. Replacing the univariate centered rank in (1) with $R_2(z)$, we define the symmetric Gini covariance as

$$\text{cov}_g(X, Y) := 2\mathbb{E}XR_2(Z). \quad (2)$$

Note that $\text{cov}_g(X, Y) = 2\text{cov}(X, R_2(Z))$ if $H$ is continuous. Dually, $\text{cov}_g(Y, X) = 2\mathbb{E}YR_1(Z)$ can also be taken as the definition of the symmetric Gini covariance between $X$ and $Y$. Indeed,

$$\text{cov}_g(X, Y) = 2\mathbb{E}XR_2(Z) = 2\mathbb{E}(X_1\mathbb{E}\frac{Y_1 - Y_2}{||Z_1 - Z_2||}|Z_1) = 2\mathbb{E}X_1\frac{Y_1 - Y_2}{||Z_1 - Z_2||}$$

$$= -2\mathbb{E}X_2\frac{Y_1 - Y_2}{||Z_1 - Z_2||} = \mathbb{E}[\frac{(X_1 - X_2)(Y_1 - Y_2)}{||Z_1 - Z_2||}] = \text{cov}_g(Y, X), \quad (3)$$

where $Z_1 = (X_1, Y_1)^T$ and $Z_2 = (X_2, Y_2)^T$ are independent copies of $Z = (X, Y)^T$ from $H$. In addition, we define

$$\text{cov}_g(X, X) := 2\mathbb{E}XR_1(Z) = \mathbb{E}\frac{(X_1 - X_2)^2}{||Z_1 - Z_2||}; \quad (4)$$

$$\text{cov}_g(Y, Y) := 2\mathbb{E}YR_2(Z) = \mathbb{E}\frac{(Y_1 - Y_2)^2}{||Z_1 - Z_2||}. \quad (5)$$

We see that not only the Gini covariance between $X$ and $Y$ but also Gini variances of $X$ and $Y$ are defined jointly through the spatial rank. Dang, Sang and Weatherall (2015) considered
the Gini covariance matrix \( \Sigma_g = 2 \mathbb{E} \mathbf{Z} \mathbf{r}^T(\mathbf{Z}) \). The covariances defined in (2), (4) and (5) are elements of \( \Sigma_g \) for two dimensional random vectors. Rather than the assumption of a finite second moment in the usual covariance and variance, the Gini counterparts assume only the first moment, hence being more suitable for heavy-tailed distributions. A related covariance matrix is the spatial sign covariance matrix (SSCM), which requires a location parameter to be known but no assumption on moments (Visuri, Koivunen and Oja, 2000).

Particularly if \( Z \) is a one dimensional random variable, we have \( \text{cov}_g(Z,Z) = \mathbb{E} |Z_1 - Z_2| \), which reduces to GMD. In this sense, we may view the symmetric Gini covariance as a direct generalization of GMD to two variables.

2.3. Symmetric Gini correlation

Using the symmetric Gini covariance defined by (2), we propose a symmetric Gini correlation coefficient as follows.

**Definition 2.** \( Z = (X,Y)^T \) is a bivariate random vector from the distribution \( H \) with finite first moment and non-degenerate marginal distributions, then the symmetric Gini correlation between \( X \) and \( Y \) is

\[
\rho_g(X,Y) := \frac{\text{cov}_g(X,Y)}{\sqrt{\text{cov}_g(X,X) \text{cov}_g(Y,Y)}} = \frac{\mathbb{E} X R_d(Z)}{\sqrt{\mathbb{E} X R_1(Z) \mathbb{E} Y R_d(Z)}}. \tag{6}
\]

**Theorem 1.** For a bivariate random vector \( (X,Y)^T \) from \( H \) with finite first moment, \( \rho_g \) has the following properties:

1. \( \rho_g(X,Y) = \rho_g(Y,X) \).
2. \( -1 \leq \rho_g(X,Y) \leq 1 \).
3. If \( X, Y \) are independent, then \( \rho_g(X,Y) = 0 \).
4. If \( Y = aX + b \) and \( a \neq 0 \), then \( \rho_g = \text{sgn}(a) \).
5. \( \rho_g(aX + b, aY + d) = \rho_g(X,Y) \) for any constants \( b, d \) and \( a \neq 0 \). Measure \( \rho_g \) is sensitive to a heterogeneous change, i.e., \( \rho_g(aX, cY) \neq \rho_g(X,Y) \) for \( a \neq c \). In particular, \( \rho_g(X,Y) = -\rho_g(aX, -aY) = -\rho_g(-aX, aY) \).

The proof is relegated to the Appendix. Theorem 1 shows that the symmetric Gini correlation has all of the properties of the Pearson correlation coefficient except Property 5. It loses the invariance property under heterogeneous changes because of the Euclidean norm in the spatial rank function. To overcome this drawback, we give the affine invariant version of the \( \rho_g \) in Section 5. Compared with the Pearson correlation, as we will see in Section 3, the Gini correlation is more robust in terms of its influence function.

2.4. Symmetric Gini correlation for elliptical distributions

The relationship between Kendall’s \( \tau \) and the linear correlation coefficient \( \rho, \tau = 2/\pi \arcsin(\rho) \), holds for all elliptical distributions. So \( \rho = \sin(\pi \tau/2) \) provides a robust estimation method for \( \rho \) by estimating \( \tau \) (Lindskog et al., 2003). This motivates us to explore the relationship between the symmetric Gini correlation \( \rho_g \) and the linear correlation coefficient \( \rho \) under elliptical distributions.

A \( d \)-dimensional continuous random vector \( Z \) has an elliptical distribution if its density function is of the form

\[
f(z|\mu, \Sigma) = |\Sigma|^{-1/2} g((z - \mu)^T \Sigma^{-1}(z - \mu)), \tag{7}
\]
where $\Sigma$ is the scatter matrix, $\mu$ is the location parameter and the nonnegative function $g$ is the density generating function. An important property for the elliptical distribution is that the nonnegative random variable $R = \|\Sigma^{-1/2}(Z - \mu)\|$ is independent of $U = \{\Sigma^{-1/2}(Z - \mu)\}/R$, which is uniformly distributed on the unit sphere. When $d = 1$, the class of elliptical distributions coincides with the location-scale class. For $d = 2$, let $Z = (X, Y)^T$ and $\Sigma_{i,j}$ be the $(i, j)$ element of $\Sigma$, then the linear correlation coefficient of $X$ and $Y$ is $\rho = \rho(X, Y) := \frac{\Sigma_{12}}{\sqrt{\Sigma_{11} \Sigma_{22}}}$. If the second moment of $Z$ exists, then the scatter parameter $\Sigma$ is proportional to the covariance matrix. Thus the Pearson correlation $\rho_p$ is well defined and is equal to the parameter $\rho$ in the elliptical distributions. If $\Sigma_{11} = \Sigma_{22} = \sigma^2$, we say $X$ and $Y$ are homogeneous, and $\Sigma$ can then be written as $\Sigma = \sigma^2 \begin{pmatrix} 1 & \rho \\ \rho & 1 \end{pmatrix}$. In this case, if $\rho = \pm 1$, $\Sigma$ is singular and the distribution reduces to an one-dimensional distribution.

The following theorem states the relationship between $\rho_g$ and $\rho$ under elliptical distributions.

**Theorem 2.** If $Z = (X, Y)^T$ has an elliptical distribution $H$ with finite first moment and the scatter matrix $\Sigma = \sigma^2 \begin{pmatrix} 1 & \rho \\ \rho & 1 \end{pmatrix}$, then we have

$$
\rho_g = k(\rho) = \begin{cases} 
\rho & \text{if } \rho = 0, \pm 1, \\
\frac{1}{\rho} + \frac{\rho - 1}{\rho} \frac{E(K(\frac{2\rho}{\rho + 1}))}{E(\frac{2\rho}{\rho + 1})} & \text{otherwise,}
\end{cases}
$$

where

$$
E(K(x)) = \int_0^{\pi/2} \frac{1}{\sqrt{1 - x^2 \sin^2 \theta}} \, d\theta \quad \text{and} \quad E(E(x)) = \int_0^{\pi/2} \sqrt{1 - x^2 \sin^2 \theta} \, d\theta
$$

are the complete elliptic integral of the first kind and the second kind, respectively.

The relationship (8) holds only for $\Sigma$ with $\Sigma_{11} = \Sigma_{22}$ because of the loss of invariance property of $\rho_g$ under the heterogeneous changes (Theorem 1). Note that for any elliptical distribution, the regular Gini correlations are equal to $\rho$. Schechtman and Yitzhaki (1987) proved that $\gamma(X, Y) = \gamma(Y, X) = \rho$ for bivariate normal distributions, but their proof can be modified for all elliptical distributions. Based on the spatial sign covariance matrix, Dürrre, Vogel and Fried (2015) considered a spatial sign correlation coefficient, which equals to $\rho$ for elliptical distributions.

Figure 1 plots the proposed symmetric Gini correlation $\rho_g$ as a function of $\rho$ under homogeneous elliptical distributions with finite second moment. In comparison, we also plot Pearson $\rho_p$ and Kendall’s $\tau$ against $\rho$. All correlations are increasing in $\rho$. It is clear that $|\tau| < |\rho_g| < |\rho_p| = |\rho|$. With (8), the estimate $\hat{\rho}_g$ of $\rho_g$ can be corrected to ensure Fisher consistency by using the inversion transformation $k^{-1}(\hat{\rho}_g)$, denoted as $\hat{\rho}^g$. In the next section, we study the influence function of $\rho_g$, which can be used to evaluate robustness and efficiency of the estimators $\hat{\rho}_g$ in any distribution and that of $\hat{\rho}^g$ under elliptical distributions.

3. INFLUENCE FUNCTION

The influence function (IF) introduced by Hampel (1974) is now a standard tool in robust statistics for measuring effects on estimators due to infinitesimal perturbations of sample distribution.
functions (Hampel et al., 1986). For a cdf $H$ on $\mathbb{R}^d$ and a functional $T : H \mapsto T(H) \in \mathbb{R}^m$ with $m \geq 1$, the IF of $T$ at $H$ is defined as

$$
\text{IF}(z; T, H) = \lim_{\varepsilon \downarrow 0} \frac{T((1 - \varepsilon)H + \varepsilon \delta_z) - T(H)}{\varepsilon}, \quad z \in \mathbb{R}^d,
$$

where $\delta_z$ denotes the point mass distribution at $z$. Under regularity conditions on $T$ (Hampel et al., 1986; Serfling, 1980), we have $\mathbb{E}_H \{\text{IF}(Z; T, H)\} = 0$ and the von Mises expansion

$$
T(H_n) - T(H) = \frac{1}{n} \sum_{i=1}^n \text{IF}(z_i; T, H) + o_p(n^{-1/2}), \quad (9)
$$

where $H_n$ denotes the empirical distribution based on sample $z_1, ..., z_n$. This representation shows the connection of the IF with robustness of $T$, observation by observation. Furthermore, (9) yields asymptotic $m$-variate normality of $T(H_n)$.

$$
\sqrt{n}(T(H_n) - T(H)) \xrightarrow{d} N(0, \mathbb{E}_H \{\text{IF}(Z; T, H)\text{IF}(Z; T, H)^T\}) \quad \text{as } n \to \infty. \quad (10)
$$

To find the influence function of the symmetric Gini correlation defined in (6), let $T_1(H) = 2\mathbb{E}X R_1(Z)$, $T_2(H) = 2\mathbb{E}X R_2(Z)$, $T_3(H) = 2\mathbb{E}Y R_3(Z)$ and $h(t_1, t_2, t_3) = t_2/\sqrt{t_1t_3}$. Then $\rho_g = T(H) = h(T_1, T_2, T_3)$. Denote the influence function of $T_i$ as $L_i(x, y) = \text{IF}((x, y)^T; T_i, H)$ for $i = 1, 2, 3$. 

Figure 1: Pearson $\rho_p$, Kendall’s $\tau$ and symmetric Gini $\rho_g$ correlation coefficients versus $\rho$, the correlation parameter of homogeneous elliptical distributions with finite second moment.
Theorem 3. For any distribution \( H \) with finite first moment, the influence function of \( \rho_g = T(H) \) is given by

\[
IF((x, y)^T; \rho_g, H) = -\frac{\rho_g}{T_1} \left( \frac{L_1(x, y)}{T_1} - \frac{2L_2(x, y)}{T_2} + \frac{L_3(x, y)}{T_3} \right)
\]

\[
= -\frac{\rho_g}{2} \left( \frac{1}{T_1} \int \frac{2(x-x_1)^2}{\sqrt{(x-x_1)^2 + (y-y_1)^2}} dH(x_1, y_1) \right)
\]

\[
- \frac{1}{T_2} \int \frac{4(x-x_1)(y-y_1)}{\sqrt{(x-x_1)^2 + (y-y_1)^2}} dH(x_1, y_1)
\]

\[
+ \frac{1}{T_3} \int \frac{2(y-y_1)^2}{\sqrt{(x-x_1)^2 + (y-y_1)^2}} dH(x_1, y_1) \right).
\]

Note that each of \( L_i(x, y) \) is approximately linear in \( x \) or \( y \). Comparing with the quadratic effects in the Pearson’s correlation coefficient (Devlin, Gnanadesikan and Kettering, 1975),

\[
IF((x, y)^T; \rho_p, H) = \frac{(x-\mu_X)(y-\mu_Y)}{\sigma_X \sigma_Y} - \frac{1}{2} \rho \left[ \frac{(x-\mu_X)^2}{\sigma_X^2} + \frac{(y-\mu_Y)^2}{\sigma_Y^2} \right],
\]

\( \rho_g \) is more robust than the Pearson correlation. However, \( \rho_g \) is not as robust as Kendall’s \( \tau \) correlation since the influence function of \( \rho_g \) is unbounded. Kendall’s \( \tau \) correlation has a bounded influence function (Croux and Dehon, 2010), which is \( IF((x, y)^T; \tau, H) = 2(2P_H[(x - X)(y - Y) > 0] - 1 - \tau) \). In this sense, \( \rho_g \) is more robust than \( \rho_p \) but less robust than \( \tau \).

Figure 2 displays the influence function of each correlation coefficient for the bivariate normal distribution with \( \mu_x = \mu_y = 0, \sigma_x = \sigma_y = 1 \) and \( \rho = 0.5 \).

![Figure 2: Influence functions of correlation correlations \( \rho_p, \rho_g \) and \( \tau \) for the bivariate normal distribution with \( \mu_x = \mu_y = 0, \sigma_x = \sigma_y = 1 \) and \( \rho = 0.5 \).]
Theorem 4. Let $\hat{\rho}_g(H_n) = \hat{\rho}_g$:

$$\hat{\rho}_g = \frac{\sum_{1 \leq i < j \leq n} \frac{(x_i - x_j)(y_i - y_j)}{\sqrt{(x_i - x_j)^2 + (y_i - y_j)^2} \sqrt{(x_i - x_j)^2 + (y_i - y_j)^2}}}{\sqrt{\sum_{1 \leq i < j \leq n} \frac{(x_i - x_j)^2}{(x_i - x_j)^2 + (y_i - y_j)^2} \sqrt{\sum_{1 \leq i < j \leq n} \frac{(y_i - y_j)^2}{(x_i - x_j)^2 + (y_i - y_j)^2}}}.$$ 

Using the same notation as in Section 3, we have the following central limit theorem of the sample symmetric Gini correlation $\hat{\rho}_g$.

**Theorem 5.** Let $z_1, z_2, ..., z_n$ be a random sample from 2-dimensional distribution $H$ with finite second moment. Then $\hat{\rho}_g$ is an unbiased, $\sqrt{n}$-consistent estimator of $\rho_g$. Furthermore, $\sqrt{n}(\hat{\rho}_g - \rho_g) \xrightarrow{d} N(0, v_g)$ as $n \to \infty$, where

$$v_g = \mathbb{E}[IF((X, Y)^T, \rho_g, H)]^2 = \frac{\rho_g^2}{4} \left( \frac{1}{T_1^2} \mathbb{E}[L_1^2(X, Y)] + \frac{4}{T_2^2} \mathbb{E}[L_2^2(X, Y)] \right) + \frac{4}{T_3^2} \mathbb{E}[L_3^2(X, Y)\mathbb{E}[L_1(X, Y) L_2(X, Y)] + \frac{2}{T_1 T_3} \mathbb{E}[L_1(X, Y) L_3(X, Y) L_3(X, Y) \right].$$

Although (10) implies Theorem 4, it is hard to check regularity conditions for the von Mises expansion (9). Instead, we prove it in the Appendix using the multivariate delta method and the asymptotic normality of the sample Gini covariance matrix, which is based on the $U$-statistics theory (Dang et al., 2015).

For an elliptical distribution $H$, Theorem 2 shows that $\hat{\rho}_g$ is not a Fisher consistent estimator of $\rho$. We need to consider the inverse transformation $\hat{\rho}_g = k^{-1}(\hat{\rho}_g)$, where the function $k$ is given in (8). Applying the delta method, we obtain the $\sqrt{n}$-consistency of estimator $\hat{\rho}_g$ for $\rho$.

**Theorem 5.** Let $z_1, z_2, ..., z_n$ be a sample from elliptical distribution $H$ with finite second moment and $\Sigma = \sigma^2 \begin{pmatrix} 1 & \rho \\ \rho & 1 \end{pmatrix}$. Then $\hat{\rho}_g = k^{-1}(\hat{\rho}_g)$ is unbiased and a $\sqrt{n}$-consistent estimator of $\rho$. Moreover, $\sqrt{n}(\hat{\rho}_g - \rho) \xrightarrow{d} N(0, [1/k'(\rho)]^2 v_g)$ as $n \to \infty$, where the function $k$ is given in (8), $v_g$ is given in Theorem 4, and $k'(\rho)$ is

$$k'(\rho) = \frac{-3(\rho + 1)EE^2(\frac{2\rho}{\rho + 1}) + 4EE(\frac{2\rho}{\rho + 1})EK(\frac{2\rho}{\rho + 1}) + (\rho - 1)EK^2(\frac{2\rho}{\rho + 1})}{2(\rho + 1)\rho^2 EE^2(\frac{2\rho}{\rho + 1})}.$$

Theorem 5 provides an estimator based on $\hat{\rho}_g$ for the correlation parameter for elliptical distributions. The asymptotic variance $[k'(\rho)]^{-2} v_g$ can be used to evaluate the asymptotic efficiency of $\hat{\rho}_g$.

4.1. Asymptotic efficiency

To compare relative efficiency, we present the asymptotic variances (ASV) of the other three estimators of $\rho$ including Pearson’s estimator $\hat{\rho}_p$, the regular Gini correlation estimator $\hat{\rho}_g$, and Kendall’s estimator $\hat{\rho}_\tau$. 

---

*The Canadian Journal of Statistics / La revue canadienne de statistique* 

DOI:
Witting and Müller-Funk (1995) established asymptotic normality for the regular sample Pearson correlation coefficient $\hat{\rho}_p$:

$$
\sqrt{n}(\hat{\rho}_p - \rho) \xrightarrow{d} N(0, v_p) \text{ as } n \to \infty,
$$

where

$$
v_p = (1 + \frac{\rho^2}{2}) \frac{\sigma_{x1}^2}{\sigma_{x1}^2 \sigma_{y1}^2} + \frac{\rho^2}{4} \left( \frac{\sigma_{x1}^2 \sigma_{y1}^2}{\sigma_{x1}^2} + \frac{\sigma_{y1}^2 \sigma_{y1}^2}{\sigma_{y1}^2} - \frac{4\sigma_{x1} \sigma_{y1} \sigma_{y1} \sigma_{y1}}{\sigma_{x1}^2 \sigma_{y1}^2} \right),
$$

and $\sigma_{k\ell} = E[(X - EX)^k(Y - EY)^\ell]$. The Pearson correlation estimator requires a finite fourth moment on the distribution to evaluate its asymptotic variance. For bivariate normal distributions, the asymptotic variance $v_p$ simplifies to $(1 - \rho^2)^2$.

An estimator $\hat{\rho}_\gamma$ of the regular Gini correlation $\gamma(X, Y)$ is

$$
\hat{\rho}_\gamma = \frac{\binom{n}{2}^{-1} \sum_{1 \leq i < j \leq n} h_1(z_i, z_j)}{\binom{n}{2}^{-1} \sum_{1 \leq i < j \leq n} h_2(z_i, z_j)},
$$

where

$$
h_1(z_1, z_2) = \left| (x_1 - x_2)I(y_1 > y_2) + (x_2 - x_1)I(y_2 > y_1) \right| / 4,
$$

$$
h_2(z_1, z_2) = |x_1 - x_2| / 4.
$$

Using U-statistic theory, Schechtman and Yitzhaki (1987) provided the asymptotic normality:

$$
\sqrt{n}(\hat{\rho}_\gamma - \rho_\gamma) \xrightarrow{d} N(0, v_\gamma) \text{ as } n \to \infty,
$$

with

$$
v_\gamma = (4/\theta_2^2)\zeta_1(\theta_1) + (4\theta_1^2/\theta_2^2)\zeta_2(\theta_2) - (8\theta_1/\theta_2^2)\zeta_3(\theta_1, \theta_2),
$$

where

$$
\theta_1 = \text{cov}(X, G(Y)), \quad \theta_2 = \text{cov}(X, F(X)),
$$

$$
\zeta_1(\theta_1) = E_{z_1}\{E_{z_2}[h_1(Z_1, Z_2)]\}^2 - \theta_1^2,
$$

$$
\zeta_2(\theta_2) = E_{z_1}\{E_{z_2}[h_2(Z_1, Z_2)]\}^2 - \theta_2^2,
$$

$$
\zeta_3(\theta_1, \theta_2) = E_{z_1}\{E_{z_2}[h_1(Z_1, Z_2)]E_{z_2}[h_2(Z_1, Z_2)]\} - \theta_1 \theta_2.
$$

Under elliptical distributions, $\gamma(X, Y) = \gamma(Y, X) = \rho$, hence the asymptotic variance of $\hat{\rho}_\gamma$ is $v_\gamma$. For a normal distribution, Xu et al. (2010) provided an explicit formula for $v_\gamma$, given by

$$
v_\gamma = \pi/3 + (\pi/3 + 4\sqrt{3})\rho^2 - 4\rho \arcsin(\rho/2) - 4\rho^2 \sqrt{1 - \rho^2}.
$$

Borovskikh (1996) presented the asymptotic normality of the estimator $\hat{\tau}$:

$$
\sqrt{n}(\hat{\tau} - \tau) \xrightarrow{d} N(0, v_\tau) \text{ as } n \to \infty,
$$

with

$$
v_\tau = 4E\{E^2_{x_1}\{\text{sgn}(X_2 - X_1)(Y_2 - Y_1)\}\} - 4E^2\{\text{sgn}(X_2 - X_1)(Y_2 - Y_1)\}.
$$
Applying the delta method to $\hat{\rho}_\tau = \sin(\pi \hat{\tau}/2)$, we obtain the asymptotic variance of $\hat{\rho}_\tau$ to be $\frac{\pi^2}{4}(1 - \rho^2)^2$. Under a normal distribution, the asymptotic variance of $\hat{\rho}_\tau$ is $\pi^2(1 - \rho^2)\left[\frac{1}{5} - \frac{1}{\sqrt{\pi}} \arcsin^2(\frac{\rho}{\sqrt{2}})\right]$ (Croux and Dehon, 2010).

We compare the asymptotic efficiency of the four estimators $\hat{\rho}^g$, $\hat{\rho}_\gamma$, $\hat{\rho}_\tau$ and $\hat{\rho}_p$ under three bivariate elliptical distributions (7): the normal distributions with $g(t) = \frac{1}{2\pi} e^{-t^2/2}$; the $t$-distributions with $g(t) = \frac{1}{2\pi} (1 + t/\nu)^{-\nu/2-1}$, where $\nu$ is the degrees of freedom; and the Kotz type distribution with $g(t) = \frac{1}{2\pi} e^{-\sqrt{t}}$. The normal distribution is the limiting distribution of the $t$-distributions as $\nu \to \infty$. The Kotz type distribution is a bivariate generalization of the Laplace distribution with the tail region fatness between that of the normal and $t$ distributions (Fang, Kotz and Hg, 1987). We consider only elliptical distributions because all four estimators $\hat{\rho}^g$, $\hat{\rho}_\gamma$, $\hat{\rho}_\tau$ and $\hat{\rho}_p$ are Fisher consistent for parameter $\rho$. The estimators for non-elliptical distributions may estimate different quantities, resulting in their asymptotic variances being incomparable.

### Table 1: Asymptotic relative efficiencies (ARE) of estimators $\hat{\rho}^g$, $\hat{\rho}_\tau$ and $\hat{\rho}_p$ relative to $\hat{\rho}_p$ for different distributions, with asymptotic variance (ASV($\hat{\rho}_p$)) of Pearson estimator $\hat{\rho}_p$.

Without loss of generality, we consider only cases with $\rho > 0$. Listed in Table 1 are asymptotic variances (ASV) of Pearson estimator $\hat{\rho}_p$, and asymptotic relative efficiencies (ARE) of estimators $\hat{\rho}^g$, $\hat{\rho}_\gamma$, and $\hat{\rho}_\tau$ relative to $\hat{\rho}_p$ for different elliptical distributions under the homogeneous assumption, where the asymptotic relative efficiency of one estimator with respect to another is defined as $\text{ARE}(\hat{\rho}_1, \hat{\rho}_2) = \text{ASV}(\hat{\rho}_2)/\text{ASV}(\hat{\rho}_1)$. The asymptotic variance of each estimator is obtained using a combination of numeric integration and Monte Carlo simulation.

Table 1 shows that the asymptotic variances of $\hat{\rho}_p$, $\hat{\rho}^g$, $\hat{\rho}_\gamma$ and $\hat{\rho}_\tau$ all decrease as $\rho$ increases. When $\rho = 1$, every estimator is equal to 1 without any estimation error. Asymptotic variances increase for $t$ distributions as the degrees of freedom $\nu$ decrease. Under normal distributions, the Pearson correlation estimator is the maximum likelihood estimator of $\rho$, thus is most efficient asymptotically. The symmetric Gini estimator $\hat{\rho}^g$ is high in efficiency with ARE’s greater than 93%; it is more efficient than Kendall’s estimator $\hat{\rho}_\gamma$. For heavy-tailed distributions, the symmetric Gini estimator is more efficient than Pearson’s estimator $\hat{\rho}_p$. The AREs of the symmetric Gini estimator are close to those of Kendall’s estimator $\hat{\rho}_\gamma$ for Kotz samples. Comparing with the regular Gini correlation estimator, the proposed measure has higher efficiency for all cases except for $\rho = 0.1$ under normal and $t(15)$ distributions, in which cases the efficiency is about 2.4% and 1.2% lower, respectively. These results may be explained by the fact that the joint spatial rank
used in \( \hat{\rho}^g \) takes more dependence information than the marginal rank used in \( \hat{\rho} \).

In summary, the proposed symmetric Gini estimator has nice asymptotic behavior that well balances between efficiency and robustness. It is more efficient than the regular Gini, which is also symmetric under elliptical distributions.

### 4.2. Finite sample efficiency

We conduct a small simulation to study the finite sample efficiencies of the symmetric Gini, regular Gini, Kendall’s \( \tau \) and Pearson correlation estimators. \( M = 3000 \) samples of two different sample sizes, \( n = 30, 300 \), are drawn from \( t \)-distributions with 1, 3, 5, 15 and \( \infty \) degrees of freedom and from the Kotz distribution. We use the R Package “mnormt” to generate samples from multivariate \( t \) and normal distributions (referred to as \( t(\infty) \) in Table 2). For the Kotz sample, we first generate uniformly distributed random vectors on the unit circle by \( \mathbf{u} = (\cos \theta, \sin \theta)^T \) with \( \theta \) in \([0, 2\pi]\), and then generate \( \mathbf{r} \) from a Gamma distribution with \( \alpha = 2 \) (the shape parameter) and \( \beta = 1 \) (the scale parameter). Hence \( \Sigma^{1/2} \mathbf{r} + \mu \) is a sample from a bivariate Kotz(\( \mu, \Sigma \)) distribution. For additional details, see Dang et al. (2015).

For each sample \( m \), each estimator \( \hat{\rho}^{(m)} \) is calculated and the root mean squared error (RMSE) of the estimator is computed as

\[
RMSE(\hat{\rho}) = \sqrt{\frac{1}{M} \sum_{m=1}^{M} (\hat{\rho}^{(m)} - \rho)^2}.
\]

The procedure is repeated 100 times for computing the mean and the standard deviation of \( \sqrt{n} \text{RMSE} \). In Table 2, we report the mean and standard deviation (in parentheses) of \( \sqrt{n} \text{RMSE} \) of correlation estimators \( \hat{\rho}^g, \hat{\rho}_\gamma, \hat{\rho}_\tau \) and \( \hat{\rho}_p \) when the scatter matrix is homogeneous with \( \Sigma = \sigma^2 \begin{pmatrix} 1 & \rho \\ \rho & 1 \end{pmatrix} \). The case of \( n = \infty \) corresponds to the asymptotic standard deviation of each estimator that can be obtained from Table 1. Since \( \hat{\rho}^g \) cannot be given explicitly due to the inverse transformation involved in \( \hat{\rho}^g = k^{-1}(\hat{\rho}_g) \), we numerically obtain \( \hat{\rho}^g \) by creating a correspondence between \( s \) and \( t \), where \( s = k(t) \) and \( t \) is a very fine grid on \([0, 1]\). \( \hat{\rho}_g \) is computed using the R package “ICSNP” spatial.rank function.

In Table 2, the \( \sqrt{n} \text{RMSE} \)s demonstrate an increasing trend as \( \rho \) decreases or as the degrees of freedom \( \nu \) decrease for \( t \) distributions. For \( n = 300 \), the behavior of each estimator is similar to its asymptotic efficiency behavior. For example, for \( n = 300 \) and \( \rho = 0.5 \) under the normal distribution, the \( \sqrt{n} \text{RMSE} \) of \( \hat{\rho}_p \) is 0.7534 which is close to the asymptotic standard deviation 0.7504. We include heavy-tailed \( t(1) \) and \( t(3) \) distributions in the simulation to demonstrate finite sample behavior of Pearson and Gini estimators when their asymptotic variances may not exist. \( \sqrt{n} \text{RMSE} \) of \( \hat{\rho}_p \) is about twice that of \( \hat{\rho}^g \) for \( n = 300 \) with both \( t(1) \) and \( t(3) \) distributions. For the \( t(1) \) distribution, \( \hat{\rho}_p \) is much better than the others in terms of \( \sqrt{n} \text{RMSE} \). When the sample size is small (\( n = 30 \)), \( \hat{\rho}^g \) performs the best. The \( \sqrt{n} \text{RMSE} \)s of \( \hat{\rho}^g \) are smaller than that of \( \hat{\rho}_p \) even under heavy-tailed \( t(3) \) distributions. \( \hat{\rho}^g \) has a smaller \( \sqrt{n} \text{RMSE} \) than the Pearson correlation estimator for the normal distribution with \( \rho = 0.1 \) and all other distributions. The symmetric Gini estimator \( \hat{\rho}^g \) has smaller \( \sqrt{n} \text{RMSE} \) than the regular Gini estimator \( \hat{\rho}_g \) for all cases we consider. The simulation demonstrates superior finite sample behavior of the proposed estimator.
Table 2: The mean and standard deviation (in parentheses) of $\sqrt{n}$RMSE of $\hat{\rho}_n$, $\hat{\rho}_r$, $\hat{\rho}_\tau$ and $\hat{\rho}_p$ under different distributions with a homogeneous scatter matrix.

</table>
5. THE AFFINE INVARIANT VERSION OF SYMMETRIC GINI CORRELATION

The proposed $\rho_g$ in Section 2.3 is only invariant under translation and homogeneous change. We now provide an affine invariant version of $\rho_g$, denoted as $\rho_G$, in order to gain the invariance property under heterogeneous changes. This is based on the affine equivariant (AE) Gini covariance matrix $\Sigma_G$ proposed by Dang et al. (2015).

The basic idea of $\Sigma_G$ is that the Gini covariance matrix for standardized data should be proportional to the identity matrix $I$. That is, $\mathbb{E}(\Sigma_G^{-1/2}Z)r_t(\Sigma_G^{-1/2}Z) = cI$, where $c$ is a positive constant. In other words, the AE version of the Gini covariance matrix is the solution of

$$
\mathbb{E} \frac{\Sigma_G^{-1/2}(Z_1 - Z_2)(Z_1 - Z_2)^T \Sigma_G^{-1/2}}{(Z_1 - Z_2)^T \Sigma_G^{-1}(Z_1 - Z_2)} = c(H)I,
$$

where $c(H)$ is a constant depending on $H$. In this way, the matrix valued functional $\Sigma_G(\cdot)$ is a scatter matrix in the sense that for any nonsingular matrix $A$ and vector $b$, $\Sigma_G(AB + b) = A\Sigma_G(Z)A^T$.

Let $Z = (X, Y)^T$ be a bivariate random vector with distribution function $H$ and $\Sigma_G := \begin{pmatrix} G_{11} & G_{12} \\ G_{21} & G_{22} \end{pmatrix}$ be the solution of (11). Then the affine invariant version of $\rho_g$ is defined as $\rho_G(X, Y) = \frac{G_{21}}{\sqrt{G_{11}G_{22}}}$. Since the value of $c(H)$ in (11) does not change the value of $\rho_G(X, Y)$, without loss of generality, assume $c(H) = 1$.

**Theorem 6.** For any bivariate random vector $Z = (X, Y)^T$ having an elliptical distribution $H$ with finite first moment, $\rho_G(aX, bY) = \text{sgn}(ab)\rho_G(X, Y)$ for any $ab \neq 0$.

**Remark 1.** Under elliptical distributions, $\rho_G = \rho$. This is true since $\Sigma_G = \Sigma$ for elliptical distributions.

When a random sample $z_1, z_2, \ldots, z_n$ is available, replacing $H$ with its empirical distribution $H_n$ in (11) yields the sample counterpart $\hat{\Sigma}_G$, and hence the sample $\hat{\rho}_G$ is obtained accordingly. We obtain $\hat{\Sigma}_G$ by a common re-weighted iterative algorithm:

$$
\hat{\Sigma}_G^{(t+1)} = \frac{2}{n(n-1)} \sum_{1 \leq i < j \leq n} \frac{(z_i - z_j)(z_i - z_j)^T}{(z_i - z_j)^T(\hat{\Sigma}_G^{(t)})^{-1}(z_i - z_j)}.
$$

The initial value can take $\hat{\Sigma}_G^{(0)} = I_d$. The iteration stops when $\|\hat{\Sigma}_G^{(t+1)} - \hat{\Sigma}_G^{(t)}\| < \varepsilon$ for a pre-specified number $\varepsilon > 0$, where $\| \cdot \|$ can take any matrix norm.

Next, we study finite sample efficiency of $\hat{\rho}_G$ under the same simulation setting as in Section 4.2 except that the scatter matrix is heterogeneous. The scatter matrix of each elliptical distribution is $\Sigma = \begin{pmatrix} 1 & 2\rho \\ 2\rho & 4 \end{pmatrix}$. Table 3 reports $\sqrt{n}\text{RMSE}$ of correlation estimators $\hat{\rho}_G$, $\hat{\rho}_\tau$, $\hat{\rho}_c$ and $\hat{\rho}_p$.

The numbers in the last three columns are very close to those in Table 2 because $\hat{\rho}_\tau$, $\hat{\rho}_c$ and $\hat{\rho}_p$ are affine invariant. $\sqrt{n}\text{RMSEs}$ of $\hat{\rho}_G$ are also close to $\sqrt{n}\text{RMSE}$ of $\hat{\rho}^b$ for $n = 300$, but are larger than those for $n = 30$ and $\rho = 0.1$. The loss of finite sample efficiency of $\hat{\rho}_G$ for a small sample size under low dependence $\rho$ is probably caused by the iterative algorithm in the computation of $\hat{\rho}_G$. The problem is even worse with the $t(1)$ distribution where the first moment does not exist.

As the value of $\rho$ increases, the $\sqrt{n}\text{RMSE}$ of each estimator decreases for all distributions. Under Kotz and $t(15)$ distributions, the affine invariant Gini estimator $\hat{\rho}_G$ is the most efficient; under $t(5)$ distribution, the $\sqrt{n}\text{RMSE}$ of $\hat{\rho}_G$ is smaller than that of Kendall’s $\hat{\rho}_\tau$ when $\rho = 0.9$. For

</tbody>
</table>
the normal distributions, $\hat{\rho}_G$ is almost as efficient as $\hat{\rho}_p$ when $\rho = 0.9$. The affine invariant Gini correlation estimator shows a good finite sample efficiency. Again, the proposed Gini correlation estimator has smaller $\sqrt{n}$RMSEs than the regular Gini correlation estimator in all cases.

6. APPLICATION

For the purposes of illustration, we apply the symmetric Gini correlations to the famous Fisher’s Iris data which is available in R. The data set consists of 50 samples from each of three species of Iris (Setosa, Versicolor and Virginica). Four features are measured in centimeters from each sample: sepal length (Sepal L.), sepal width (Sepal W.), petal length (Petal L.), and petal width (Petal W.). The mean and standard deviation of each of the variables for all data and each species data are listed in Table 4. All the three species have similar sizes in sepal. Setosa has a much smaller petal size than the other two species. We shall study the correlation of the variables for each Iris species.

| Table 4: Summary Statistics of Variables in Iris Data |
|-----------------|-----------------|-----------------|-----------------|
|                  | Mean            | Standard Deviation |
|                  | All             | Setosa           | Versicolor       | Virginica       |
| Sepal L.         | 5.843           | 5.006            | 5.936           | 6.588           |
| Sepal W.         | 3.057           | 3.428            | 2.770           | 2.974           |
| Petal L.         | 3.758           | 1.462            | 4.260           | 5.552           |
| Petal W.         | 1.199           | 0.246            | 1.326           | 2.026           |

For each Iris species, we compute different correlation measures for all pairs of variables. Since standard deviations of four features are quite different, the affine equivariant version of symmetric gini correlation estimator $\hat{\rho}_G$ is used. For each pair of variables $X$ and $Y$, we also calculate the Pearson correlation, Kendall’s $\tau$ and the two regular gini correlation estimators, denoted as $\hat{\gamma}_{1,2}$ ($\hat{\gamma}(X, Y)$) and $\hat{\gamma}_{2,1}$ ($\hat{\gamma}(Y, X)$). All correlation estimators are listed in Table 5.

From Table 5 we see that compared with the other two species, Iris Setosa has higher correlation between sepal length and sepal width, but has lower correlation between sepal length and petal length. Versicolor has much larger correlation between petal length and petal width than the other two species. Virginica has the highest correlation between sepal length and petal length among the three species.

Kendall’s $\tau$ correlation estimate is the smallest among all correlation estimates across all pairs and across all species. Two regular Gini correlation estimates are quite different especially between sepal width and petal length in Iris Virginica species. The difference is as high as 0.159. One might perform a hypothesis test on exchangeability of two variables by testing $\gamma_{1,2} = \gamma_{2,1}$ (Schechtman, Yitzhaki and Artsev, 2007). The p-value of the test is 0.0113, which provides strong evidence to reject the hypothesis of exchangeability of two variables sepal width and petal length in Iris Virginica. We also observe that $\hat{\rho}_G$ and $\hat{\rho}_p$ tend to have a similar pattern across variable pairs and across species. For example, for all six pairs of variables in Iris Setosa, $\hat{\rho}_G$ is large or small whenever $\hat{\rho}_p$ is large or small. In other words, the correlation ranking across variable pairs provided by the Pearson correlation is the same as the ranking by the proposed symmetric Gini correlation. However, such a pattern is not shared by any two correlations from $\hat{\rho}_G$, $\hat{\tau}$, $\hat{\gamma}_{1,2}$ and $\hat{\gamma}_{2,1}$. Also, values of $\hat{\rho}_G$ are larger than values of $\hat{\rho}_p$ in most cases.

DOI: The Canadian Journal of Statistics / La revue canadienne de statistique
7. CONCLUSION

In this paper we propose symmetrized Gini correlation $\rho_g$ and study its properties. The relationship between $\rho_g$ and $\rho$ is established when the scatter matrix, $\Sigma$, is homogeneous. The affine invariant version $\rho_G$ is also proposed to deal with the case when $\Sigma$ is heterogeneous. Asymptotic normality of the proposed estimators are established. The influence function reveals that $\rho_g$ is more robust than the Pearson correlation while it is less robust than Kendall’s $\tau$ correlation. Comparing with the Pearson correlation estimator, the regular Gini correlation estimator and the Kendall’s $\tau$ estimator of $\rho$, the proposed estimators balance well between efficiency and robustness and provide an attractive option for measuring correlation. Numerical studies demonstrate that the proposed estimators have satisfactory performance under a variety of situations. In particular, the symmetric Gini estimators are more efficient than the regular Gini estimators.

We comment that the symmetric Gini correlation $\rho_g$ is not limited to elliptical distributions. Theorems 1, 3 and 4 hold for any bivariate distribution with a finite first moment. Under elliptical distributions, the linear correlation parameter $\rho$ is well defined and all four estimators are Fisher consistent. Hence their asymptotic variances are comparable and can be used for evaluating relative asymptotic efficiency among the estimators.

The proposed symmetric Gini correlation has some disadvantages. Although its formulation is natural, the symmetric Gini loses an intuitive interpretation. It is more difficult to compute than the Pearson correlation, especially when $X$ and $Y$ are heterogeneous. In this case, an iterative scheme is required to obtain the affine invariant version of symmetric Gini correlation. When applying the proposed measure, one may consider the trade-off among efficiency, robustness, computation and interpretability.
BIBLIOGRAPHY

APPENDIX

**Proof of Theorem 1.** The first property is obvious. Hölder’s inequality implies

\[ \left| \mathbb{E} \left( \frac{X_1 - X_2}{\|Z_1 - Z_2\|} \frac{Y_1 - Y_2}{\|Z_1 - Z_2\|} \right) \right| \leq \sqrt{\mathbb{E} \left( \frac{X_1 - X_2}{\|Z_1 - Z_2\|} \right)^2 \mathbb{E} \left( \frac{Y_1 - Y_2}{\|Z_1 - Z_2\|} \right)^2} \] 

and hence \( |\rho_g(X, Y)| \leq 1 \).

DOI: *The Canadian Journal of Statistics / La revue canadienne de statistique*
Let \((X_i, Y_i), i = 1, 2,\) be independent copies of \((X, Y),\) then \(\text{cov}_g(X, Y) = 2\mathbb{E} \frac{X_1(Y_1 - Y_2)}{||Z_1 - Z_2||} = 2\mathbb{E} \frac{X_1Y_1}{||Z_1 - Z_2||} - 2\mathbb{E} \frac{X_1Y_2}{||Z_1 - Z_2||} = 0\) by symmetry. Hence \(\rho_g(X, Y) = 0.\)

If \(Y = aX + b,\) then
\[
\rho_g(X, Y) = \frac{\mathbb{E}(X_1 - X_2)(Y_1 - Y_2)}{\sqrt{\mathbb{E}(X_1 - X_2)^2 \mathbb{E}(Y_1 - Y_2)^2}} = \frac{a}{\sqrt{a^2 + 1}} \mathbb{E}|X_1 - X_2| = \text{sgn}(a).
\]
\[
\rho_g(aX + b, aY + d) = \rho_g(X, Y)
\]
can be obtained from
\[
\text{cov}_g(aX + b, aY + d) = \mathbb{E} \frac{a^2(X_1 - X_2)(Y_1 - Y_2)}{a||Z_1 - Z_2||} = |a|\text{cov}_g(X, Y),
\]
\[
\text{cov}_g(aX + b, aX + b) = |a|\text{cov}_g(X, X),
\]
\[
\text{cov}_g(aY + d, aY + d) = |a|\text{cov}_g(Y, Y).
\]

By (3), (4) and (5), it is easy to see the remainder of property 5.

**Proof of Theorem 2.** To prove the theorem, we need a result from Dang et al. (2015). They consider the Gini covariance matrix \(\Sigma_g = 2\mathbb{E}Z\Lambda^T(Z).\) Their Theorem 2.1 states that if the scatter matrix \(\Sigma\) has the spectral decomposition \(VAV^T\) with \(\Lambda = \text{diag}(\lambda_1, \lambda_2),\) then \(\Sigma_g = V\Lambda_g V^T\) with \(\Lambda_g = \text{diag}(\lambda_{g,1}, \lambda_{g,2})\) and
\[
\lambda_{g,i} = c(H)E \left[ \frac{\lambda_i u_i^2}{\sqrt{\lambda_1 u_1^2 + \lambda_2 u_2^2}} \right], \quad i = 1, 2 \tag{A1}
\]
where \(u = (u_1, u_2)^T\) is uniformly distributed on the unit circle, \(\lambda_i\)'s are the eigenvalues of \(\Sigma\) and \(c(H)\) is a constant depending on the distribution \(H.\) Here the eigenvalues of \(\Sigma\) are \(\lambda_1 = \sigma^2(1 - \rho)\) and \(\lambda_2 = \sigma^2(1 + \rho),\) and the corresponding eigenvectors are \((1, -1)^T\) and \((1, 1)^T.\) Consequently, \(\rho_g = \frac{\lambda_{g,1}}{\lambda_{g,2}}.\) Obviously, if \(\rho = \pm 1,\) either \(\lambda_1\) or \(\lambda_2\) is zero. With (A1), we have \(\rho_g = \pm 1 = \rho.\) If \(\rho = 0,\) then \(\lambda_1 = \lambda_2,\) and hence we have \(\lambda_{g,1} = \lambda_{g,2}\) and \(\rho_g = 0 = \rho.\) When \(|\rho| < 1\) and \(\rho \neq 0,\) let \(u_1 = \cos \theta\) and \(u_2 = \sin \theta,\) then \(\theta\) is uniformly distributed in \([0, 2\pi].\) With (A1), we have
\[
\rho_g = \frac{\int_0^{2\pi} \frac{1}{2\pi} (1 - \rho) \cos^2 \theta - (1 + \rho) \sin^2 \theta d\theta}{\int_0^{2\pi} \frac{1}{2\pi} \sqrt{(1 - \rho) \cos^2 \theta + (1 + \rho) \sin^2 \theta} d\theta} = \frac{\int_0^{\pi/2} \frac{\rho - \rho \cos 2\theta}{\sqrt{1 - \rho \cos 2\theta}} d\theta}{\int_0^{\pi/2} \sqrt{1 - \rho \cos 2\theta} d\theta} = \frac{1}{\rho} + \rho - 1 \frac{EK(2\rho/(\rho + 1))}{\rho \cdot E(2\rho/(\rho + 1))}.\]

**Proof of Theorem 3.** Let \(\tilde{H} = (1 - \epsilon)H + \epsilon \delta_{(x,y)},\) then
\[
T_1(\tilde{H}) = 2 \int \frac{x_1(x_1 - x_2)}{(x_1 - x_2)^2 + (y_1 - y_2)^2} d\tilde{H}(x_2, y_2) d\tilde{H}(x_1, y_1) = 2(1 - \epsilon)^2 T_1(H) + 2 \epsilon (1 - \epsilon) \int \frac{(x - x_2)^2}{(x - x_2)^2 + (y - y_2)^2} dH(x_2, y_2).
\]

We have
In 2015, we get

where $G$ is the matrix of $a,b,c$ being the matrix of $X,Y$. As a result, the operator that stacks the columns of $G$ is affine equivariant, $\Sigma_G(AZ) = A\Sigma_G(Z)A^T$. As a result, $\rho_G(aX,bY) = \frac{\text{sgn}(ab)\rho_G(X,Y)}{\sqrt{\sigma_{G11}\sigma_{G22}}}$. Working out the explicit form of $\rho_G$ completes the proof.

Proof of Theorem 4. Let $\Sigma_g$ be the Gini covariance matrix of $Z = (X,Y)^T$ and $\hat{\Sigma}_g = \begin{pmatrix} G^2_x & G_{xy} \\ G_{xy} & G^2_y \end{pmatrix}$ be the sample Gini covariance matrix for sample $\{Z_i\}_{i=1}^n$. Let vec$(M)$ be the operator that stacks the columns of $M$ to form a vector. According to Theorem 4.1 of Dang et al. (2015), we get

$$\sqrt{n}(\text{vec}(\hat{\Sigma}_g) - \text{vec}(\Sigma_g)) \xrightarrow{d} N_4(0, V),$$

where $V = 4E[\psi(Z)\psi^T(Z)]$, $\psi(z) = \text{vec}\left(\frac{\text{vec}(z-z\|z\|)}{\|z\|} - \Sigma_g\right)$. Then

$$\sqrt{n}\left\{(G^2_x, G_{xy}, G^2_y)^T - \text{cov}_g(X,X), \text{cov}_g(X,Y), \text{cov}_g(Y,Y)\right)^T\right\} \xrightarrow{d} N_3(0, V^*)$$

with $V^*$ being the matrix of $V$ deleting the third row and third column. Now, since $\rho_g = h(G^2_x, G_{xy}, G^2_y) = G_{xy}/\sqrt{G^2_xG^2_y}$, and the derivative of $h$ is $h(a,b,c) = -b/(2\sqrt{ac})(1/a, -2/b, 1/c)$, we have

$$\dot{h}(\text{cov}_g(X,X), \text{cov}_g(X,Y), \text{cov}_g(Y,Y)) = -\rho_g \frac{1}{2} \begin{pmatrix} 1 \\ \text{cov}_g(X,X) \\ -2 \text{cov}_g(X,Y) \\ 1 \text{cov}_g(Y,Y) \end{pmatrix},$$

which is denoted as $B$. Applying the delta method yields the asymptotic normality of $\hat{\rho}_g$ with the asymptotic variance $\nu_g = BV^*B^T$. Working out the explicit form of $\nu_g$ completes the proof.

Proof of Theorem 6. The proof is straightforward. Let $A$ be the diagonal matrix with the diagonal elements being $a$ and $b$. Since $\Sigma_G$ is affine equivariant, $\Sigma_G(AZ) = A\Sigma_G(Z)A^T$. As a result, $\rho_G(aX,bY) = \frac{\text{sgn}(ab)\rho_G(X,Y)}{\sqrt{\sigma_{G11}\sigma_{G22}}}$. Working out the explicit form of $\rho_G$ completes the proof.
